The Impact of Perceived Water Pollution Contribution on the Valuation of Water Quality Changes in the Northeast U.S.

Introduction

Ensuring sustainable water quality is a critical endeavor, requiring a comprehensive understanding of how individuals perceive and value water quality changes.

- Evaluate the preferences of residents regarding a specific water quality change ladders, considering the initial water quality condition and the different perceived water pollution contribution.
- Identify key characteristics among respondents of varying perceptions. By doing so, we aim to foster a more comprehensive approach to water quality management that not only considers the technical aspects but also recognizes and factors that shape individuals' perceptions and responses to environmental challenges.

Data Collection

- Our study was conducted in 245 counties spanning 11 states: MD, NJ, DE, PA, NY, CT, RI, MA, VT, NH, and ME.
- Design: 9 Blocks * 4 Scenarios
- Respondents were randomly assigned one block of choice scenarios
- Out of 7,028 valid responses, 5,602 were used in this study to conduct the Condition Logit Model

Results and Conclusions

Notes: Figure reports utility parameter values (dot) and 90% CI's (line) obtained using Conditional Logit Model. The pink ones indicate that the coefficients are statistically significant at the 90% level. The parameters shown in the figure represent coefficients associated with the interactions among miles moved from a lower category to a higher category in human use or ecological integrity ladders, skewness measure of baseline water quality, and a categorical variable indicates respondents' perceptions regarding their contribution to water pollution compared to other households, categorized as lower, similar, or higher.

- As has been shown in our previous study, individuals' marginal utility of a specific water quality improvement, as measured by miles moving from a lower category to a higher one in human use or ecological integrity ladders, are different. Furthermore, the preferences associated with a specific water quality improvement vary across the baseline distributions of water quality.
- Regarding the interactions related to respondents' perceptions, the results suggest that compared to those who perceive their contribution to be similar, those who believe their household adds more pollutants attribute significantly positive marginal utilities on specific water quality improvements in areas where the baseline water quality is lower, including boatable to swimmable, unusable to boatable in human uses, and "none or few" to "some" species, "none or few" to "many" species, "some" to "most or all" species, "many" to "most or all" species in ecological integrities.
- However, those perceiving lower contributions assign lower marginal utility to specific water quality improvements in regions where the baseline water quality is lower, although the results did not demonstrate considerable significance.
- Interestingly, higher perceived contributors are more likely to come from counties with lower economic status and lower intensity of local employment in industries that negatively impact water quality.
- Moreover, they tend to be aged 30-45, more educated, with a higher minority representation, support environmental policies, and more inclined towards conservation efforts while displaying less government trust.
